Definitions

- Measurement (*What do you know?*)
 - Assigning numbers to things, events, people, actions, etc.
- Assessment (*How do you know?*)
 - Measurements, actions, processes, data that answer the question.
- Evaluation (*How are we doing?*)
 - Comparing results and observations with goals and objectives (implied or otherwise).

Methods of Assessment

- Assessment is data collection and analysis for the purpose of demonstrating/verifying
- Really only two ways to do it:
 - Question
 - Observe
- Raw data have to be processed (statistics)

Upon Construction and Use of an LO

- This was a **good** (**bad**) LO
- Assessment: How do you know?
 - They told me they **liked** (**hated**) it.
 - They did really **well** (**poorly**) on the quiz.
 - There was a **lot** of (**little**) discussion in class on loops afterwards.
 - **Marked** (**Slight or No**) improvement from pre- to post-test.
 - Experts **approve** (**disapprove**).
 - It **covers** (**fails to cover**) the basics of the information.

Upon Construction and Use of an LO

- This LO was worth it (not worth it).
- Evaluation: Compared to what?
 - It was free (expensive).
 - It did (didn't) take much time to construct.
 - We did (didn't) get the kind of gain we were hoping for or expecting
- And the implications of the evaluation are?

Research Design

- Get help from the Internal Evaluator, Debra Davis
- Get help from education or psychology professors at your institution

Testing

- According to instructional design theory, you start curricular design from the *tests* (i.e., you teach to the test)
- Upon interaction with a given LO, the SWBAT.....
- Make it behavioral, not cognitive
 - SWBAT trace code
 - **SWBAT enjoy programming**

Testing

- Test items, collectively, should maximize variance (i.e., distinguish between students of differing ability)
- The more advanced the subject, the more difficult the items should become
 - e.g., All options are correct; choose the most correct
- No surprises on the test (in terms of content and format)

Statistics

- Select a good comparison criterion or group
- Standard statistical techniques **are** acceptable for Likert-scaled survey data
- **Don't** use NHST ($p \leq .05$)
 - Strongly influenced by sample size
 - Small p does not necessarily indicate a stronger relationship or effect, or practical significance
 - What people think it is: $P(H_0=0|\text{sample})$
 - What it actually is: $P(\text{sample}|H_0=0)$
 - How much *there* is there?

Effect Size Statistics

- For Likert or interval-level data, when comparing two groups, use **Cohen's d**
 - $M_1 - M_2 / [(s_1 + s_2) / 2]$
- For ordinal data, when comparing two groups, use **Probability of Superiority**
 - $MWU / (n_1 n_2)$
- For correlations between two groups, use **r^2**
 - $(r) (r) \times 100$ gives % of variance explained
